About MongoDB Shell environment

What is the MongoDB Shell?

What is the MongoDB Shell?

MongoDB SMongo shell, or mongosh, is an interactive JavaScript interface that allows you to interact with MongoDB instances through the command line.

Mong

oDB Shell, or mongosh, is an interactive JavaScript interface that allows you to interact with MongoDB instances through the command line. The shell can be used for data manipulation, testing queries, and administrative operations, such as maintenance of MongoDB database instances either locally or on a remote host.

MongoDB Shell is the default client for the MongoDB database server. It's a command line interface (CLI), where the input and output are all console based. Mongosh is a good tool to manipulate small sets of data

What are the features of MongoDB Shell?

MongoDB Shell features are always evolving. Key functionality now includes:

- Run all MongoDB queries from the Mongo shell.
- Manipulate data and perform administration operations.
- Issue commands using JavaScript and a related API.
- See previous commands in the Mongo shell with up and down arrow keys.
- Syntax that color codes inputs and outputs for easier reading.
- Intelligent autocomplete that helps if you can't remember a command or operator.
- Clear error messages to help you know what is wrong and where in the code problems exist.
- Contextual help, linking your direction to documentation.
- A powerful scripting environment.
- The ability to save frequently used scripts as snippets that you can reuse later.

Installing the MongoDB Shell

The MongoDB Shell gets installed when you install the MongoDB server. It is installed in the same location as the MongoDB server binary.

If you want to install it separately, you can visit the <u>MongoDB download center</u>, from there select the version and package you need, download the archive, and copy it to a location in your file system.

Mongo shell is available for all main operating systems, including:

- Windows
- Linux
- Mac OS

How to connect to a database from the MongoDB Shell

Once you've <u>downloaded and installed MongoDB</u>, you can use the mongo shell to connect with a MongoDB server that is up and running.

Note: It is required that your server is already running before you connect with it through the shell. You can start the server in CMD using the following command.

net start MongoDB

```
C:\windows\system32>net start mongodb
The MongoDB Server (MongoDB) service is starting....
The MongoDB Server (MongoDB) service was started successfully.
```

Then type mongo command

to run the shell.

Mongo

Now you are in

the Mongo shell.

If you want, you can run the mongo and mongod without the command prompt. To do this, go to the installation location and double click on the mongod and mongo applications. You will get the same result as the above.

Using different port with MongoDB Shell

The above mongo command only works if your MongoDB server runs on the default port, which is

27017. If your MongoDB server runs on a different port, you have to explicitly specify it in the command, as shown below:

mongo --port 28010

Connecting to a remote MongoDB server

Both of the above commands only work if your MongoDB server is running on the localhost. If you want to connect to a remote server, use the `-host` option with the mongo command, as shown below.

mongo --host mongodb0.example.com --port 28010

Basic MongoDB Shell commands

Now it's time to work with the Mongo shell. First, we will learn some basic mongosh commands that will help you to get started.

See current selected database - db command

Run the **db command** to see the database you are currently working with

db

Switch to a different database - use command

Run the **use command** to switch to a different database. If you don't have a database, <u>learn how to create a new database</u>.

use company

```
> use company
switched to db company
>
```

Create collections and insert data in MongoDB

You can create collections and insert data with the following MongoDB Shell command:

- db refers to the current database in use.
- employee is the collection name.
- insertOne is the method to insert a document to the collection.

db.employee.insertOne({ name: "mark" });

Fetch data in a collection - find method

Use the **find method** to fetch data in a collection. The forEach(printjson) method will print them with JSON formatting

db.employee.find().forEach(printjson)

```
> db.employee.find().forEach(printjson)
{ "_id" : ObjectId("5f736ec9cb9ff210daae2271"), "name" : "mark" }
>
```

Show all databases - show dbs command

Use the **show dbs command** to Show all databases

show dbs

```
> show dbs
admin 0.000GB
company 0.000GB
config 0.000GB
local 0.000GB
```

Get a list of help options - MongoDB help commands

One important basics MongoDB command will help you work with the Mongo shell easily: the help command. Run the help command to get a list of help options available in the mongo shell.

Help

```
help
       db.help()
db.mycoll.help()
                                           help on db methods
                                           help on collection methods
       sh.help()
                                           sharding helpers
                                          replica set helpers
administrative help
       rs.help()
       help admin
       help connect
                                          connecting to a db help

       help mr
                                           mapreduce
       show dbs
                                           show database names
       show collections
                                           show collections in current database
       show users
                                          show users in current database
       show profile
show logs
                                          show most recent system.profile entries with time >= 1ms
                                          show the accessible logger names

To get a full list

of MongoDB Shell commands that you can execute on the current database, type db.help()

```

db.printCorecolaryPerplication()
db.printCorecolaryPerplication()
db.serverStatus()
db.serve
```

We will discuss

more data manipulation commands in coming tutorials. For a full list of commands, check out the official Mongo shell page.

MongoDB Shell keyboard shortcuts

There are two important MongoDB Shell keyboard shortcuts that you should know:

- 1. **Use up and down arrows** to go back and forth in the commands history.
- 2. **Press the tab key** to get a full list of possible commands. For example, type **d** and press tab twice. You will get the following output.

```
> d

DBCommandCursor( DataConsistencyChecker( db defaultPrompt( doassert(
DBExplainQuery( Date( decodeURI( defineProperties

DBPointer( DriverSession( decodeURIComponent( defineProperty

> d
```

Disadvantages of the MongoDB Shell

Although the Mongo shell is an excellent tool for learning and testing the MongoDB server, it is difficult to be used in a production environment. Being a shell inherently carries certain disadvantages. Let's see what they are:

- The Mongo shell is strictly a console centric method of data manipulation. While some find it easy and quick, others might not find those characteristics appealing.
- If you are working on multiple sessions, you need multiple terminals.
- If the results are too long, they scroll away.
- Repetitive commands or debugging a function need the programmer to traverse the long command line history manually.

Alternatives to MongoDB Shell

So now you know the MongoDB shell has some disadvantages. At this point, you may want to know what other options are available. MongoDB developers have introduced drivers specific to each programming language to connect with the MongoDB databases when using MongoDB in your applications. You can find them here.

Additionally, many people prefer to use GUIs to work with databases nowadays. One of the best GUI tools for MongoDB is the MongoDB Compass. Some other useful GUI tools are:

- NoSQLBooster
- Robo 3T

Remember that the best MongoDB GUI depends on the task that needs to be accomplished. MongoDB Compass is the go-to option if you need to avoid the command line completely. Robo 3T is simple and well supported by the community, while NoSQLBooster is shell centric smart GUI tool.

With that, we've reached the end of this tutorial. Now, play with the shell and get practice.
